## ABSTRACT

Now a days all world suffering from a pandemic issue of COVID-19 to control these situation and to maintain the safety of ourselves we all have to take care of the two things like do not make a crowd and wear the mask properly. And to achieve this requirement of safety this paper works with the help of fog node and camera. Managing the crowd requires an intelligent monitoring technology. In this project, we propose a method to manage the crowd by counting multiple humans in the scene by head detection. In our study, we develop a system using Raspberry Pi 3 board that detects the human heads and provide a count of humans in the region using OpenCV-Python. A Haar cascade classifier is trained for human head detection.

This work also proposes a fog computing-based face mask detection system for controlling the entry of a person into a facility. The proposed system uses fog nodes to process the video streams captured at various entrances into a facility. Haar-cascade-classifiers are used to detect face portions in the video frames Each fog node deploys two MobileNet models, where the first model deals with the dichotomy between mask and no mask case. The second model deals with the dichotomy between proper mask wear and improper mask wear case and is applied only if the first model detects mask in the facial image. This two-level classification allows the entry of people into a facility, only if they wear the mask properly The results of the analysis will be helpful in managing the crowd and mask detection in the area with the help of camera.

Key words- Haar-cascade-classifiers, Adobos algorithm, head detection, mask detection tracking.

## 1 INTRODUCTION

This paper introduced the crowd analysis by counting the number of head enter in the areas. Also this paper will helpful to take care from the pandemic issue COVID-19 by detecting the mask wearing person and improper mask wearing person with the help of IOT and Camera which is used in the project. In this project we use Haar cascade amplifier for mask detection and for head detection. This study focusses on training a cascade classifier for human head detection by taking positive samples and negative samples. The trained cascade is then used to process the video frames in which the human heads are detected and the count of the humans in the scene is provided. Haar-cascade-classifiers are used to detect face portions in the video frames. Each fog node deploys two MobileNet models, where the first model deals with the dichotomy between mask and no mask case. The second model deals with the dichotomy between proper mask wear and improper mask wear case and is applied only if the first model detects mask in the facial image. This two-level classification allows the entry of people into a facility, only if they wear the mask properly.

### 1.1 Project Objectives

This Project consists of various system and technology for the better result. As it's a analysis of crowd and mask detection. it contains the fog system as well as we use the Raspberry Pie for this system along with the python. Main objective of this system is according to the area or region where it implemented. In this we try to analyse and control the crowd in particular area by notifying the movement of the people and by detecting the heads in the crowd. Also we try for the mask detection process, in which two levels are exists like proper mask wearing person and improper mask wearing person.

## 2. LITERATURE SURVEY

Detection of objects by using a cascade of simple features was mainly introduced by researchers for face detection [1], [2]. The role of Haar features extracted from an integral image in object detection is elaborated in their work. Some researchers explain a framework that can be trained for object detection [3]. He usage of face mask by the general public to impede the spread of the Corona Virus pandemic is highly essential. Wearing face mask limits the spread of virus through droplets, such as saliva or mucus

[4]. Automatic entry and access control systems based on face mask detection are of immense help at several places such as workplaces, railway stations, shopping malls. These systems help in restricting the entry of persons not wearing a mask to a facility without manual intervention. T Fog Computing is a decentralized computing and storage infrastructure that brings processing closer to the data origin [5],[6].

## **2.1 Problem Statement**

This project totally depends on the camera as well as sensors so if there is no any network range for some duration so at that time we can't analysis the crowd and movement of the people and the mask wearing people also. Also we use the camera for the analysis bt if there is a range problem then we can't able to access the data. This is the main problem of this system may occurs.

## **3.PROPOSED SYSTEM**

### **3.1 For Crowd Analysis:**

The proposed work is to develop a system for multiple head detection and human tracking by estimating the direction movement using Raspberry pi. Initially, a cascade classifier is trained offline for head detection using the samples collected from the scene. Haar features are used to train the cascade classifier through OpenCV. The proposed system uses a camera to record the crowded scene. Raspberry pi 3 uses a quad-core ARMv8 central processing unit which processes the video frame by frame to detect the presence of humans by using the previously trained cascade classifier for head detection. This process gives the count of humans present in the scene. To manage the crowd, the count of the persons is kept in track and if the count goes beyond a threshold, prevention of more people from entering the scene can be done. The detected human heads are then tracked by using the optical flow algorithm and the direction of motion of each human is indicated on the display connected to the processor

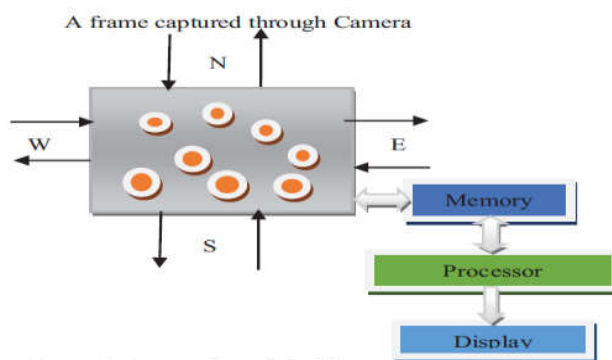

Fig. 1. Proposed model of the system.

### 3.2 for mask detection:

The proposed system employs a RPi fog node integrated with Raspberry Pi Camera and Relay Sensor at each entrance where entry control is required. The fog nodes are connected to the same Wi-Fi network. The basic architecture of the proposed system is shown in Fig. 2.2.2.1.

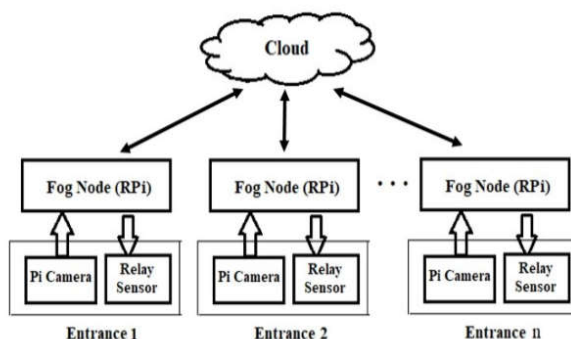

Fig. 1 The basic architecture of the proposed system

Face Mask Detection at the Fog Computing Gateway The frames in the video stream captured by Pi Camera are processed by the fog node. Whenever any face(s) is detected in the frame, the face mask detection model tries to identify whether the person(s) is wearing the mask or not. The RPi module sends a control signal to the relay to open the door, if the person wears the mask properly. The decision to open the door or not is taken completely on the fog node, and the event information can be sent to the Cloud optionally for further storage and processing.

## 4. HARDWARE AND SOFTWARE TOOLS

### 4.1 Hardware:

For hardware implementation of our study, we use Raspberry Pi board. It has a 1.2GHz 64-bit quad-core ARMv8 CPU, 802.11n Wireless LAN, Bluetooth 4.1 and Bluetooth Low Energy (BLE). It also has a 1GB RAM, 4 USB ports, 40 GPIO pins, Full HDMI port, Ethernet port, Camera interface, Display interface and a Micro SD card slot. The Raspberry Pi 3 board with camera interface.

### 4.2 Software:

The software used here is OpenCV-Python. OpenCV is a library of programming functions. It is mainly aimed at realtime computer vision. OpenCV supports a wide variety of programming languages like C++, Python, Java, etc. OpenCVPython is the Python API of OpenCV. To support various applications, OpenCV includes a statistical machine learning library.

**Fig.3 Raspberry Pi-3**

## 5. RESULTS AND DISCUSSION

In the experimental study, the cascade detector is tested on a real time video recorded in our institution.:

### A. Multiple Human Detection Using Real Time Video

Two real time videos are captured in our institution using a 12 mega pixel camera one consisting of humans and the other with no persons in the scene. Surveillance cameras in crowd are specifically positioned in a particular angle and hence video is recorded for a specified angle and then trained using that video. Each video is then segmented into frames and the frames are saved in separate directories as positive and negative. The positive images are then marked for human heads using annotation tool.

**Fig. Head Detection and crowd counting Result.**

### B. Mask Detection Using the various nodes

The face mask detection models (model-1 and model-2) are trained using different learning rates (LR) 0.001 and 0.0001 with two different numbers of epochs 10 and 20. The model-1 and model-2 training tasks have taken 34 minutes and 20 minutes respectively (with LR = 0.001 and #Epochs = 20) on RPi 4. The face detection and inference tasks for the given video frame have taken 0.3 seconds and 3.4 seconds respectively on average. Table I and Table II present the accuracy and loss values during training and validation phases of model-1 and model-2 respectively (with LR = 0.001 and #Epochs = 20). From the results in Table I and Table II, we can observe that training, validation accuracy and loss values are improving during the models' training. After few number of epochs (epoch #15 for model-1 training, and epoch #10 for model-2 training approximately), we get fluctuations in the accuracy and loss values. The variations in the accuracy and loss values are due to model overfitting with more number of epochs.

## 6. CONCLUSION

This paper presented the analysis of crowd with the mask detection using the fog node and Rpi-3. Due to this we easily conclude the crowd in the specific area using the pi Camera. The estimation of direction of movement of each person aids in human tracking. Using increased number of samples, the results are found to be efficient. The human detection and tracking can generally be used in surveillance tasks. Further improvement in this study can be done by providing re-identification of any person enterin This work also presented a proof-of-concept fog computing based face mask detection system for automatic entry and access control into a facility. The fog gateway processes the video stream captured at the entrance to recognize whether a person is wearing a mask or not.

## ACKNOWLEDGEMENT

I take this opportunity to express my profound gratitude to my esteemed project guide and , H.O.D, EnTC Department of Godavari College of Engineering, Jalgaon **Prof. Mr. H.T.Ingale** for his excellent guidance, suggestions and constructive criticism. Working under his guidance greatly contributed in improving quality of my project work and my Engineering skills. Actually he is one of such genuine person for whom my words will not be enough to express.I am extremely fortunate be involved in an exciting and challenging research project. It gave me an opportunity to work in new environment of Fluent. This project has improved my thinking and understanding capability.

I am also thankful to **Prof. V.D.Chaudhari** for his constant support and encouragement.

I am also grateful to **Prof. Dr. V. H. Patil**, the Principal of Godavari College of Engineering, Jalgaon for his constant encouragement and support.
